Abstract

Human T-cell Leukemia Virus type 1 (HTLV-1), the etiological agent of HTLV-1 Associated Myelopathy Tropical Spastic Paraparesis (HAM/TSP), is a neurodegenerative retrovirus that causes progressive spinal cord inflammation and disability. Despite its significant impact on affected populations in endemic regions, HAM/TSP remains underexplored, especially in the context of computational biology. In this study, we employed a comprehensive in silico approach to investigate hypothetical proteins (HPs) encoded by the HTLV-1 genome that may contribute to its neurotropism and pathogenicity. Through genome and proteome analysis of HTLV-1 strain ATK-1, we identified and annotated 18 hypothetical proteins using physicochemical characterization, subcellular localization, transmembrane topology, antigenicity prediction, and virulence profiling. Functional annotations revealed that several HPs may act as viral regulators, RNA-binding proteins, or immune evasion molecules. Notably, HP ATK1_RS00135 demonstrated strong virulent potential, cytoplasmic localization, and predicted interaction with host immune signalling pathways. Furthermore, molecular docking and dynamics simulation suggested that antiviral compounds such as Ribavirin and Zidovudine exhibit stable binding with HP ATK1_RS00090, indicating its potential as a repurposable drug target. This computational analysis of HTLV-1 HPs not only expands our understanding of its molecular pathogenesis but also presents novel targets for drug development and vaccine design against HAM/TSP.

Keywords: HTLV-1, Human T-cell Leukemia Virus type 1, HAM/TSP, Hypothetical Proteins, In Silico Analysis, Drug Target Identification, Molecular Docking, Protein Functional Annotation, Biomedical Engineering, Computational Biology.

Introduction

Human T-cell Leukemia Virus type 1 (HTLV-1) is a retrovirus and the etiological agent responsible for HTLV-1 Associated Myelopathy / Tropical Spastic Paraparesis (HAM/TSP), a chronic neurodegenerative disease characterized by progressive inflammation and demyelination of the spinal cord [1]. HAM/TSP leads to spastic paraparesis, sensory disturbances, and bladder dysfunction, significantly impairing the quality of life of affected individuals [2]. Globally, HTLV-1 infection is endemic in regions such as Japan, the Caribbean, South America, and parts of Africa, with an estimated 5–10 million infected individuals worldwide [3]. Despite its considerable public health impact, HAM/TSP remains underdiagnosed and poorly understood, particularly at the molecular level.[7]

HTLV-1 primarily infects CD4+ T-cells, leading to persistent infection and immune dysregulation that contribute to disease progression [4]. While several viral proteins have been characterized for their roles in viral replication and pathogenesis, approximately 20–30% of the HTLV-1 genome encodes hypothetical proteins (HPs) with unknown functions [5]. These uncharacterized proteins may play critical roles in viral persistence, immune evasion, or neurotoxicity but remain largely unexplored due to limited biochemical data.

Current therapeutic options for HAM/TSP are limited to symptomatic management, with no effective antiviral

treatment to halt disease progression [6]. This therapeutic gap underscores the urgent need to identify novel molecular targets within the HTLV-1 proteome. In this context, in silico approaches provide a powerful platform to predict functions and druggability of HPs, guiding future experimental validation and drug development efforts [7].

In this study, we conducted a comprehensive bioinformatics analysis of HTLV-1 hypothetical proteins derived from the core viral genome to predict their physicochemical properties, subcellular localization, virulence potential, and protein-protein interactions. Furthermore, molecular docking and dynamics simulations were employed to evaluate possible drug candidates against prioritized HPs.[10] Our integrative computational approach aims to uncover novel drug targets within the HTLV-1 proteome, paving the way for improved therapeutic interventions against HAM/TSP.[8]

SecretomeP 1.0f Prediction Summary

In the context of SecretomeP 1.0f analysis, nonclassically secreted proteins are characterized by a Neural Network (NN) score exceeding the standard threshold of 0.6, **without** the concurrent prediction of a signal peptide. Users are advised to consult the "Warning" column for indications of signal peptide presence as predicted by SignalP.

Prediction Results:

Table 8: Predicted Result

Name	NN- scor e	Odd s by Prio r	Weighte d	Warnin g
7M1W_1_Cha	0.87 4	5.04 4	0.010	_

The protein **7M1W_1_Chain** exhibits an NN-score of **0.874**, which significantly exceeds the threshold of 0.6, indicating a strong likelihood of non-classical secretion. No signal peptide was predicted for this sequence, as reflected by the absence of a warning, thereby supporting its classification as a non-classically secreted protein.

- Edges represent functional associations, not just physical interactions and they likely work together in same biological process

Table 10: Protein interaction chart legend

Gene Symbol	Protein Name	Function Summary
ALB	Serum albumin	Major plasma protein; binds water, ions, fatty acids, hormones, and drugs. Regulates osmotic pressure.
INSR	Insulin receptor	Tyrosine kinase receptor; mediates insulin's metabolic effects.
IRS1	Insulin receptor substrate 1	Mediates insulin signaling; activates PI3K when phosphorylated.
IGF1	Insulin-like growth factor I	Promotes cell growth; similar to insulin but more potent in growth functions.

IGF1R	IGF1 receptor	Receptor tyrosine kinase for IGF1; important for cell survival and proliferation.
IRS2	Insulin receptor substrate 2	Similar role to IRS1; mediates insulin's cellular effects.
GCG	Glucagon	Counteracts insulin; raises blood glucose during hypoglycemia.
NTRK1	Neurotrophic receptor tyrosine kinase 1	Binds NGF; critical for neuron survival and differentiation.
EGF	Epidermal growth factor	Stimulates epithelial cell growth; involved in magnesium transport.

Docking results:

Table 12: Result of Docking

Ligand	Score
H-89 Dihydrochloride	-6.6 (C5)
Suramin Sodium	-9.5(C1)
Pseudoephedrine	-4.1(C5)
2-(4-morpholinyl)-8-phenyl-	-6.6(C4)
4H-1-benzopyran-4-one	
N-(2-hydroxy-5-	-5.9(C3)
methylphenyl)-3-	
phenylpropanamide	

Results

In this study the toxicity profiling of these compounds indicated that Suramin Sodium possessed the most favorable safety characteristics, exhibiting no AMES toxicity, hepatotoxicity, or hERG inhibition. In contrast, Pseudoephedrine showed the weakest binding affinity (-4.1 kcal/mol) and was associated with hepatotoxicity and skin sensitization risks, rendering it unsuitable for therapeutic application.

Physicochemical analysis of one modeled protein (Matrix protein p19) revealed an instability index of 46.31 (indicative of instability), a basic isoelectric point (pI = 10.59), and low solubility, which may influence its behavior in a cellular environment. Structural features such as high alpha-helical content and predicted protein-protein interactions with key host signaling proteins (e.g., IGF1R, INSR) suggest functional relevance in viral replication or host manipulation.

Collectively, the results highlight as a prioritized druggable target with strong ligand-binding potential and favorable pharmacological interactions, laying the foundation for further experimental validation.

Conclusion

Based on the docking scores and toxicity profiles, Suramin Sodium emerges as the most promising inhibitor, demonstrating the strongest binding affinity (-9.5) and a favorable toxicity profile with no AMES toxicity, hERG inhibition. hepatotoxicity, or H-89 Dihydrochloride and 2-(4-morpholinyl)-8-phenyl-4H-1benzopyran-4-one show moderate binding affinities (-6.6) but are associated with notable toxicities-H-89 with hepatotoxicity and hERG II inhibition, and the morpholinyl-benzopyran derivative with a positive AMES test, indicating potential mutagenicity. N-(2hydroxy-5-methylphenyl)-3-phenylpropanamide has a slightly weaker binding score (-5.9) but stands out for its excellent safety profile, making it a potential candidate for further optimization. In contrast, Pseudoephedrine, with

the lowest docking score (-4.1) and concerns of hepatotoxicity and skin sensitization, appears least suitable as a therapeutic inhibitor.
